

Cooke City- SE face Henderson Mt

Date

Tue, 11/17/2020 - 19:53

Activity

Skiing

Test slope beneath the SE face of Henderson Mt at about 9500 ft was windloaded, 130 cm deep. Very hard icy crust layer 40 cm from surface looked like it had a storm snow then wind slab above it. We did an isolated column test - since we forgot string- and the 30x30 cm column broke on the crust layer on the 20th hit. Other than that no activity but some rollerballs as things warmed up this afternoon, and lots of wind deposition going on. Hope this is at least a little useful. I'll take pics next time!
